How to generate the Farfield Info

- define farfield monitor at one or more specified frequencies
- box surface fields (E+H) are recorded, from which in the postprocessing the farfield is calculated.

Farfield Terminology

Online Help

CST MICROWAVE STUDIO

Farfield Overview

In CST MWS the used reference for gain/directivity is an ideal spherical radiator (=isotropic antenna -> dBi), a $\lambda/2$ -Dipole has a gain of 2.2dB(i).

Some Farfield Terms

Directivity: The directivity of an antenna is officially defined as "the ratio of the radiation intensity in a given direction from the antenna to the radiation intensity averaged over all directions". At this the radiation intensity is given by the total power radiated by the antenna divided by 4π :

$$D(\theta, \varphi) = 4\pi \cdot \frac{\text{power radiated per unit solid angle}}{\text{total radiated power}}$$

Gain: Accordingly the gain is defined quite similar but related to the input or accepted power of the antenna. In case of a loss free antenna (no conductional or dielectric losses) the gain is equal to the directivity.

$$G(\theta, \varphi) = 4\pi \cdot \frac{\text{power radiated per unit solid angle}}{\text{input (accepted) power}}$$

Radiation efficiency: The antenna radiation efficiency is defined as the ratio of gain to directivity or equally the ratio between the radiated to accepted (input) power of the antenna:

$$G(\theta, \varphi) = e_{rad} \cdot D(\theta, \varphi) \quad \text{or} \quad P_{rad} = e_{rad} \cdot P_{in}$$

Total efficiency: The total efficiency is defined as the ratio of radiated to stimulated power of the antenna:

$$P_{rad} = e_{total} \cdot P_{stim}$$

Compared to the input power the stimulated power consider any occurring reflections at the feeding location.

Reflection efficiency: The reflection efficiency is defined as the ratio of input to stimulated power. In CST MICROWAVE STUDIO® this value can also be determined from the reflection factor:

$$e_{refl} = \frac{P_{in}}{P_{stim}} = \frac{e_{total}}{e_{rad}} = 1 - S_{11}^2$$

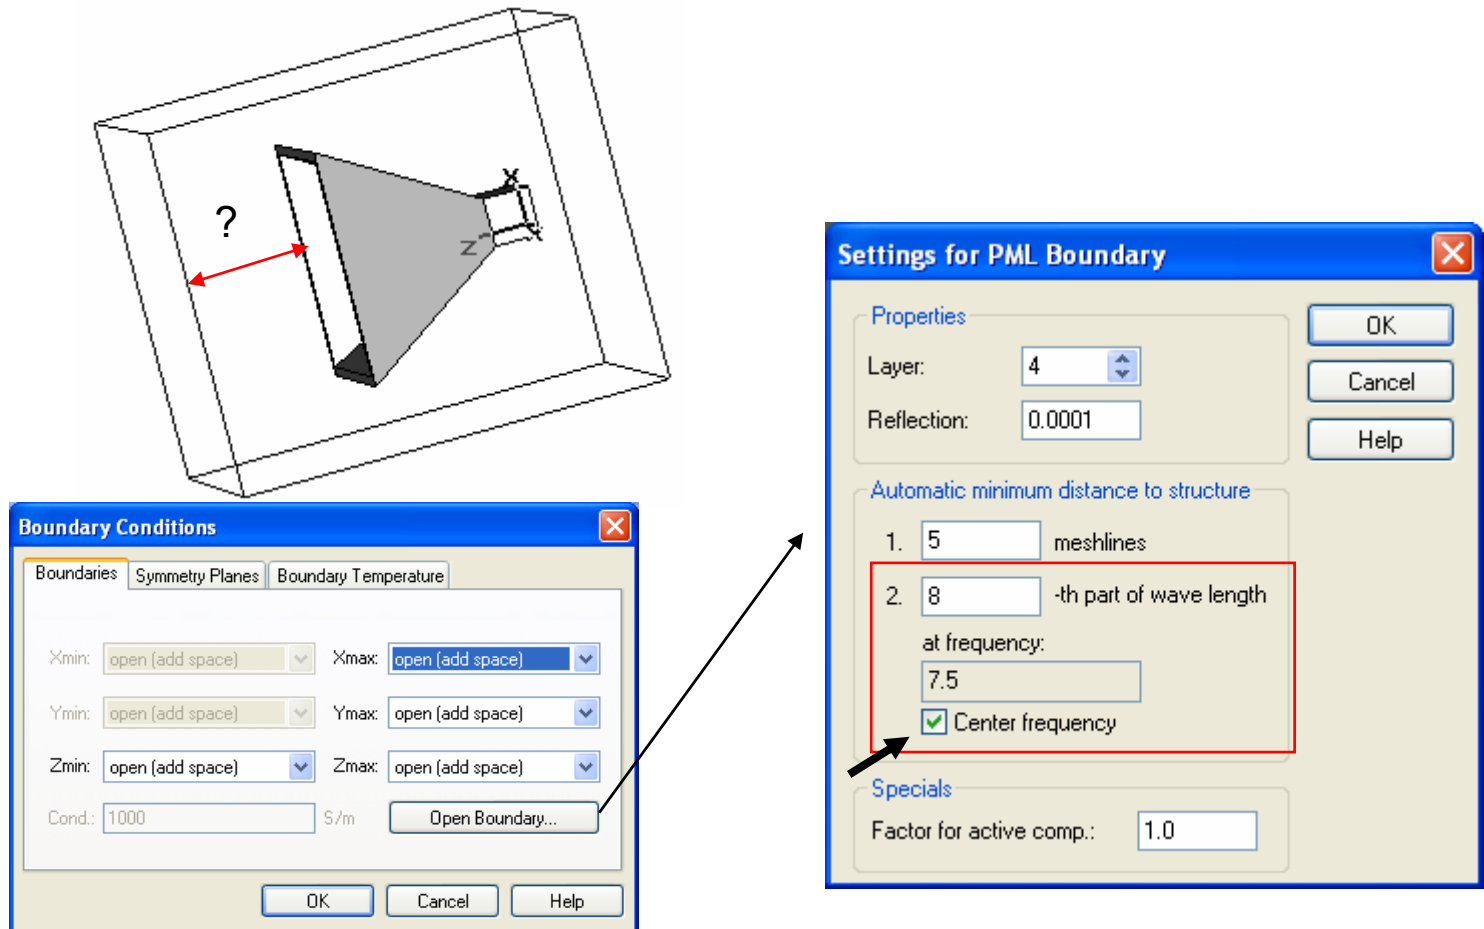

Tips & Tricks to obtain accurate farfield results

Tip 1/3 : Check Energy

- The accuracy level in the T-solver should be **-40dB**.
For larger frequency bands (eg 0-3 GHz) or bad radiation better use -60dB, so that E+H on the bounding box do not suffer from FFT/DFT truncation error.

Tip 2/3 : Check ,add. space‘

„open (add space)“ boundary ensures $\lambda/8$ space at the center frequency, for lower frequencies (bigger λ) the space needs to be increased accordingly.

Tip 3/3 : Check Balance

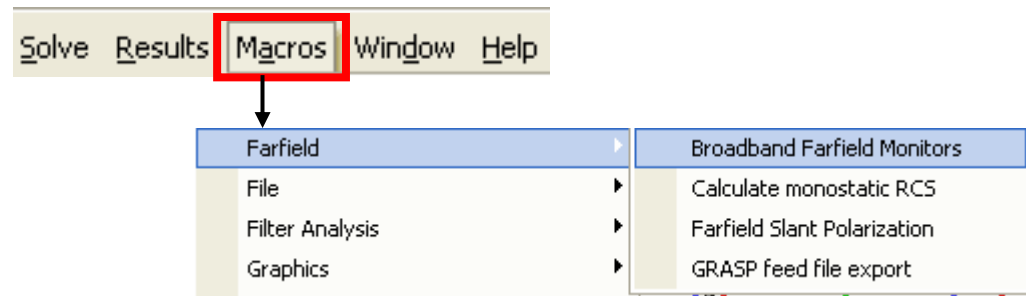

at 4.5 GHz farfield can be critical

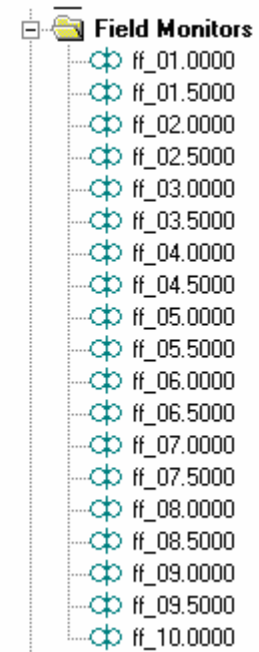

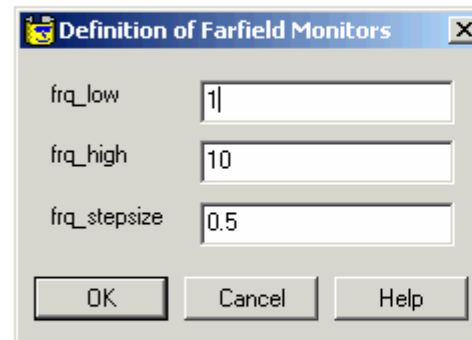

- Farfield values become critical, **if *S-Parameter balance*=1** (no power is radiated). In this case directivity and gain are calculated from dividing 0/0, which is numerically critical.
A good measure for total radiated power is: (1-balance).

How to calculate farfield Broadband at many frequencies

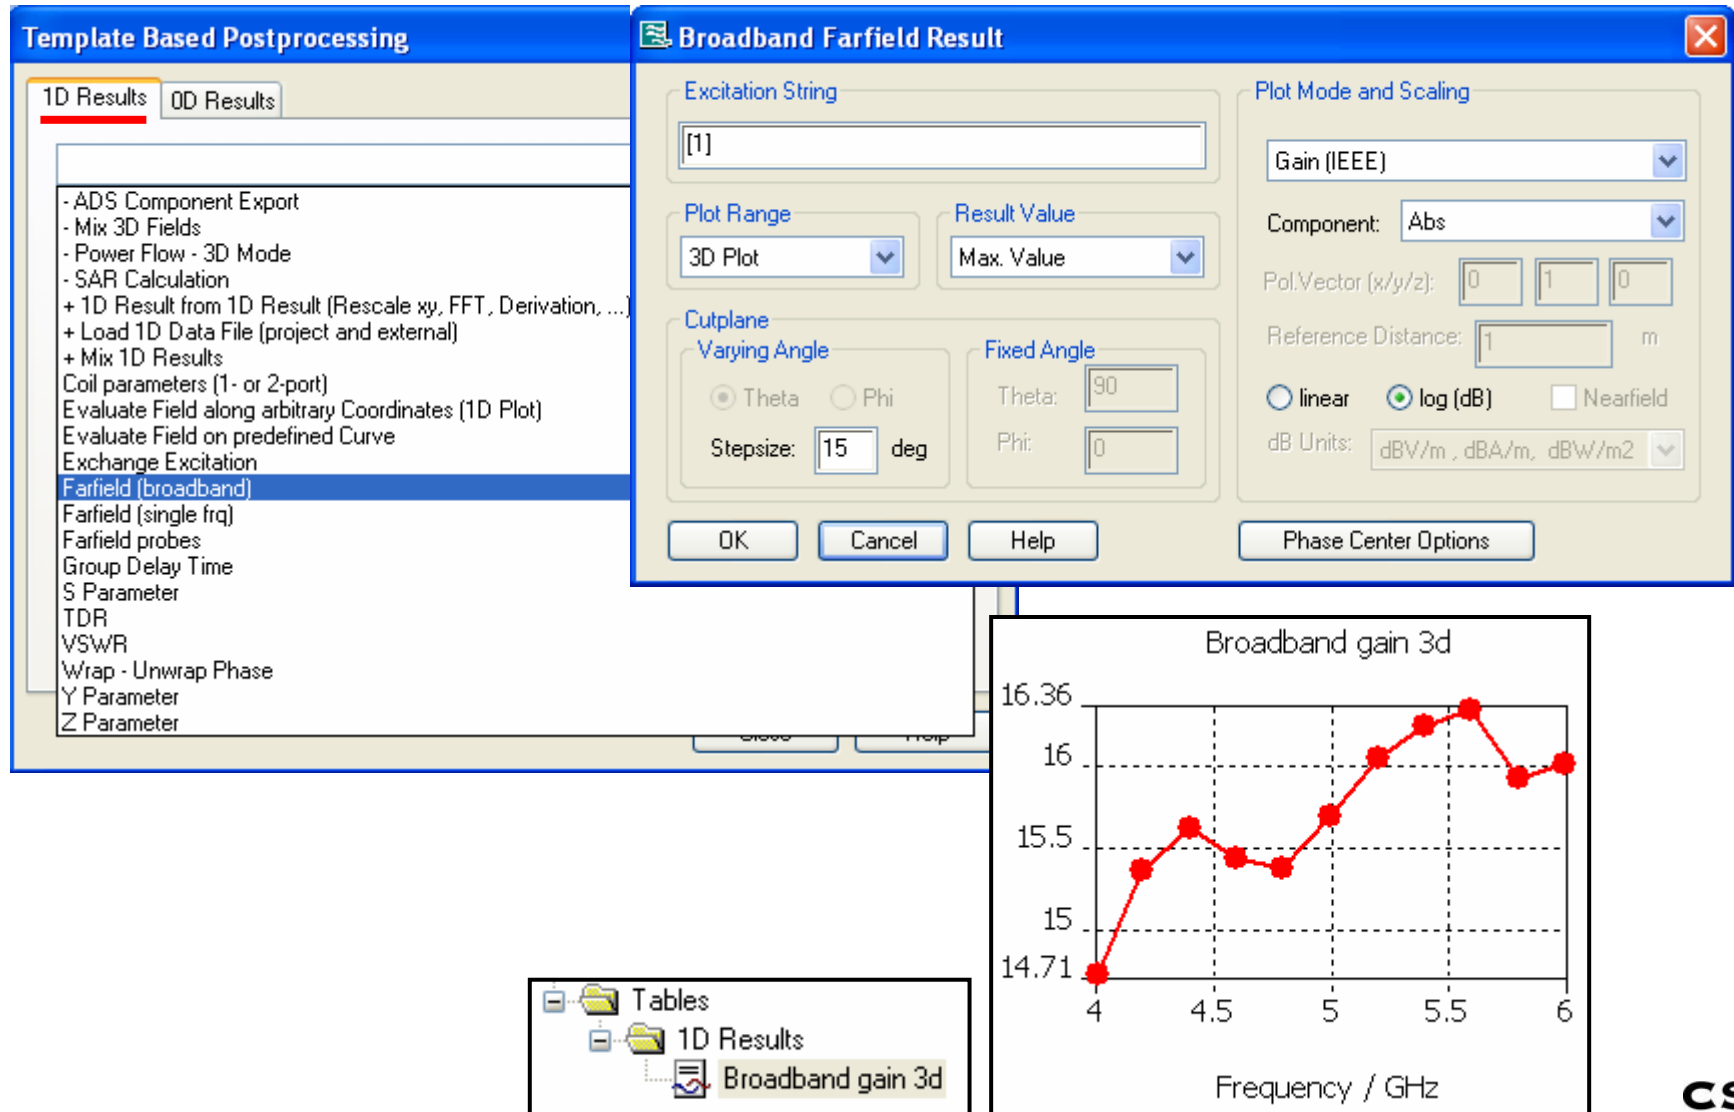

Definition of Broadband Farfield Monitors

- macro can be applied ***multiple times*** without overwriting the previous definitions, so that different frequency resolutions can be combined.

Evaluation of Broadband Farfield Monitors

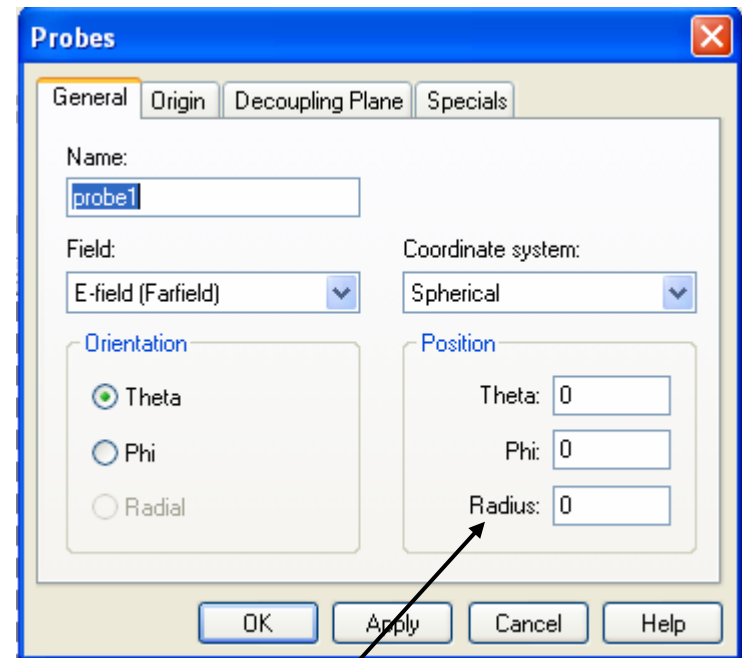

Definition of Farfield Probes

Farfield **monitors** record the radiation in ALL directions for ONE frequency.

Farfield **probes** record the radiation in ONE direction for ALL frequencies.
(recording a time signal)

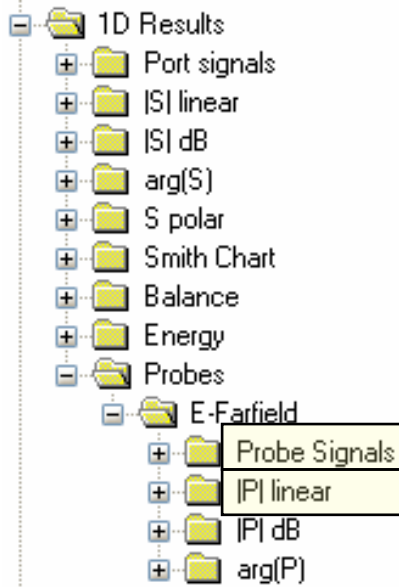

Probe	=	probe1
Type	=	Efield (farfield)
Theta	=	0
Phi	=	90
Radius	=	40

Attn: this radius is entered in the design-units (e.g. cm) and not automatically in Meter

for optimization runs.

Co & Cross Polarization

Co & Cross Polarization

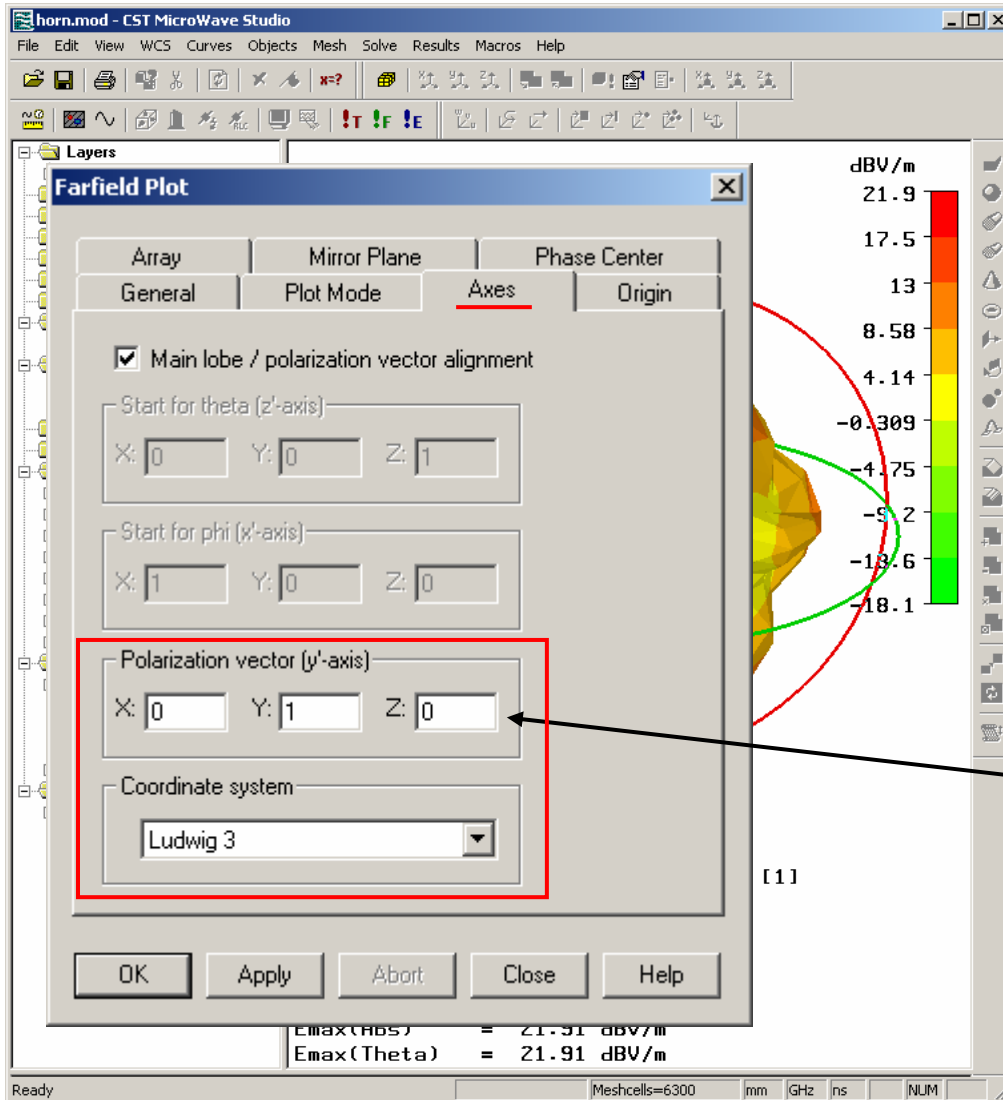

The **Co-polarized** farfield component has the same polarization as the excitation (y-oriented in our case).

The **Cross-polarized** farfield component is orthogonal to Co-pol component and mainlobe direction.

In order to use different polarizations for transmitting/receiving, an antenna design goal might be to maximize the Co-pol and minimize the cross-pol component.

Co & Cross Polarization

Adjust the Axes / coord. system

Polarization vector default direction
(the right one for our example;
arbitrary user input possible)

Co & Cross Polarization

Co pol = Ludwig 3 Vertical

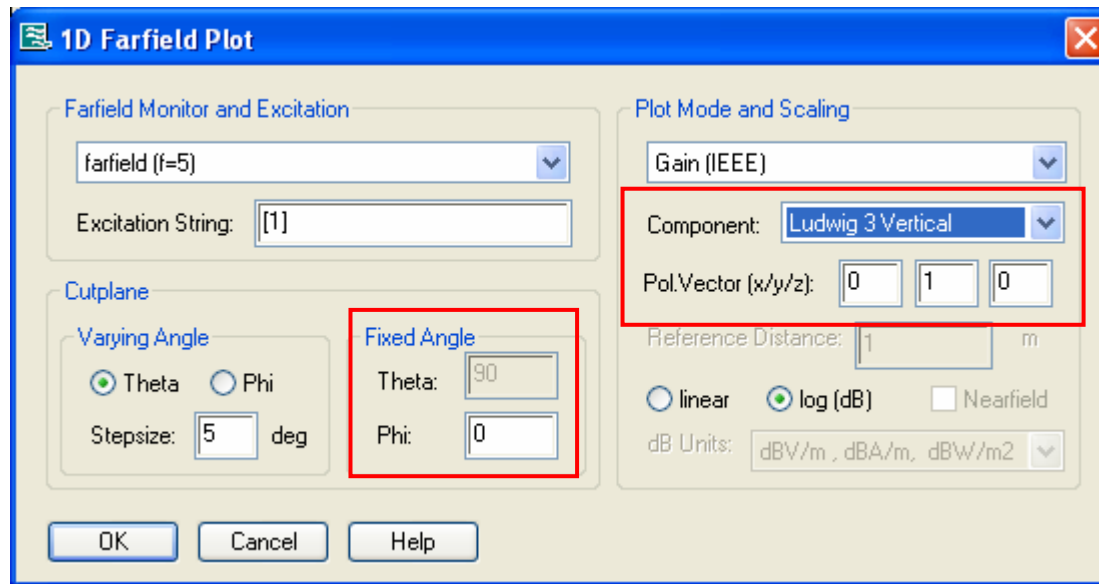

Cross pol = Ludwig 3 Horizontal

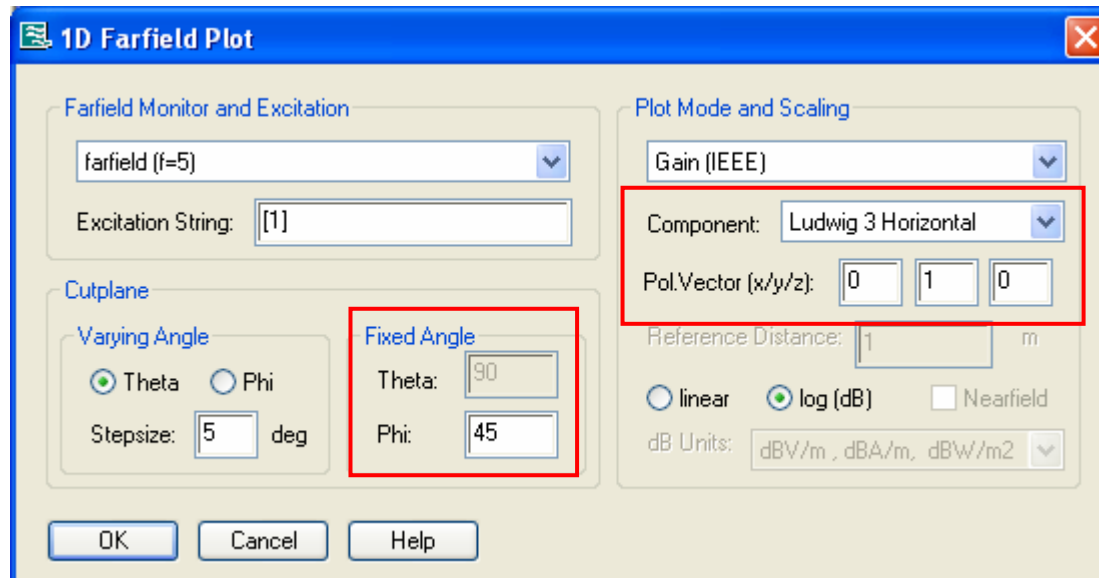

Cross polarized component is typically worse for the angles $\phi=45$ and $\phi=225$

Co & Cross Polarization

Result Templ. for Param-Sweep & Optimization

Co pol = Ludwig 3 Vertical

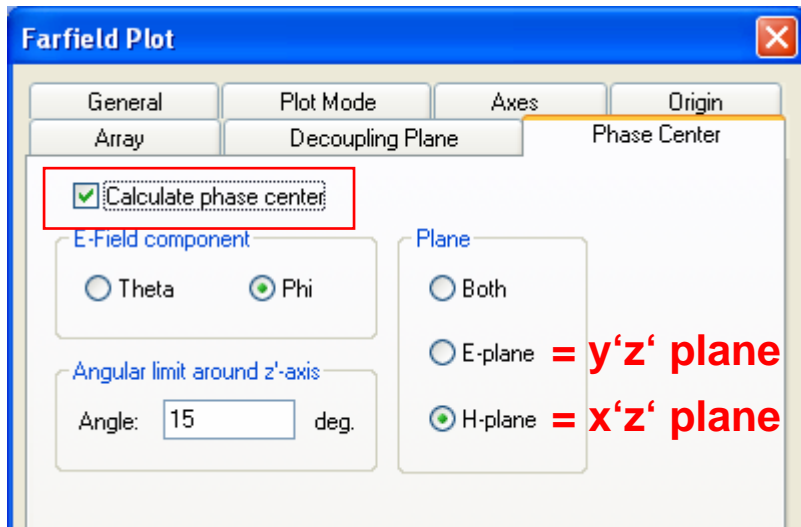

Cross pol = Ludwig 3 Horizontal

Phase Center / Grasp Export

Phase Center Calculation

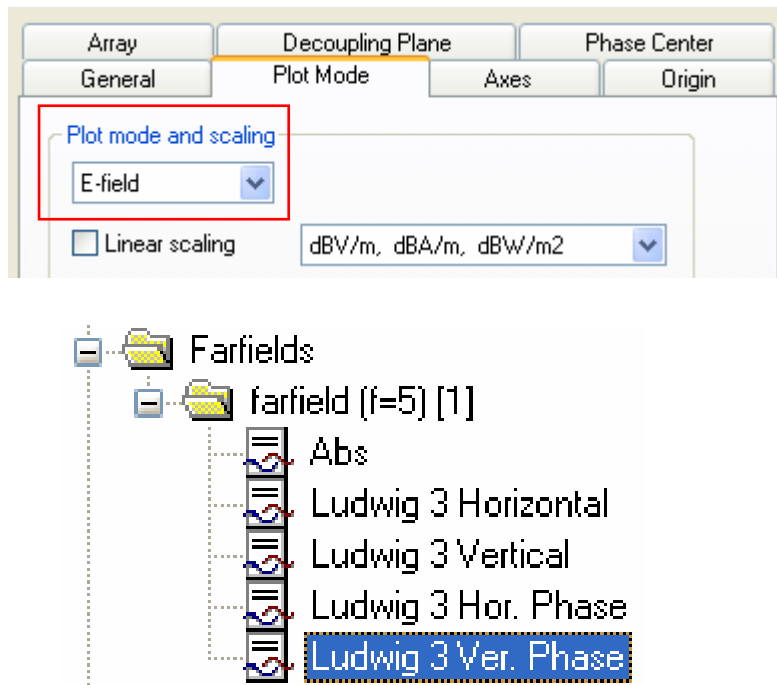

Finding the best location to place the horn inside a dish antenna. The best position is to match the **focal point of the dish** with the **phase center of the horn**.

```
Type = Farfield
Approximation = enabled (kR >> 1)
Monitor = farfield (f=5) [1]
Component = Ludwig 3 Ver. Phase
Output = E-Field(r=1m)
Frequency = 5
E_max(Theta) = 20.41 dBu/m
Phase center = (2, 1, 5.29659) Sigma 0.0829187 (H-Plane)
```

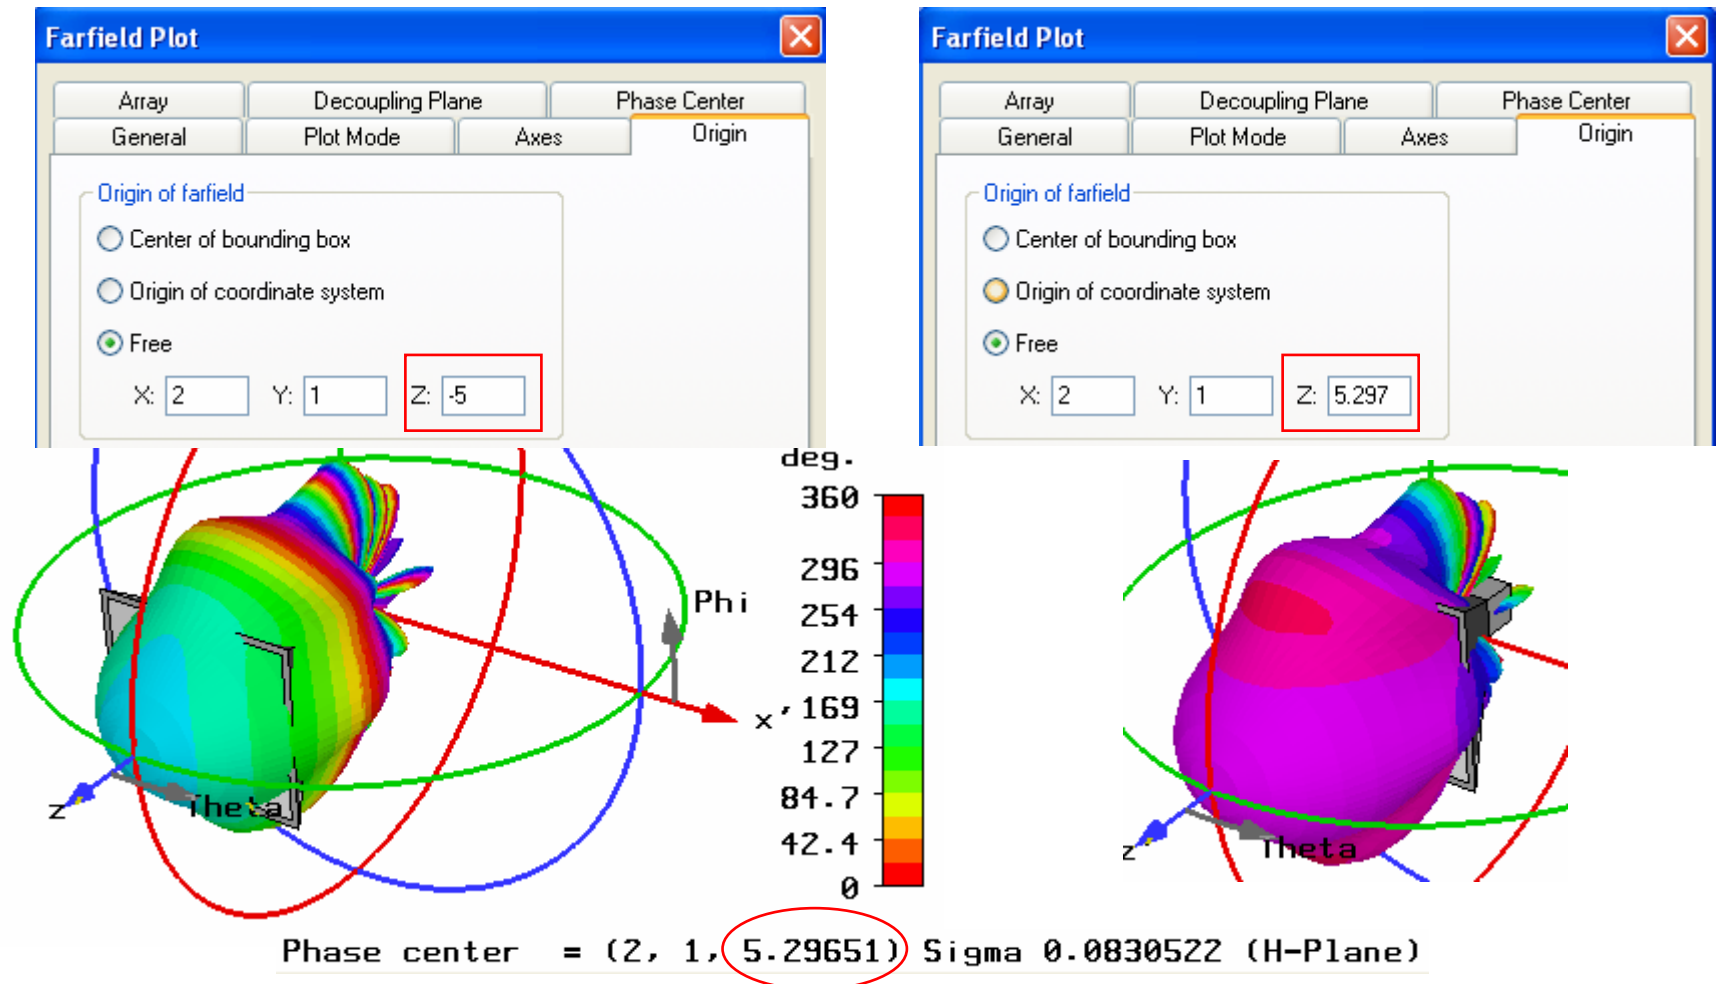

Check Phase Center by plotting Ludwig3-Ver.Phase

Plotting the Phase of Ludwig 3 Vertical
(=dominant component co-pol) does not result
in a phase 180 deg jump (=colour jump) at $\theta=0$

Check Phase Center by moving Origin into Phase Center

Ports=ALL/Modes=All + Combine Results

- requires several T-runs (-> use Distributed Computing!)
- + produces S-Parameters
- + **broadband** constant phase shift of 90 deg.
- + flexibility to get results for arbitrary am/ph combination in postprocessing

Simultaneous Excitation

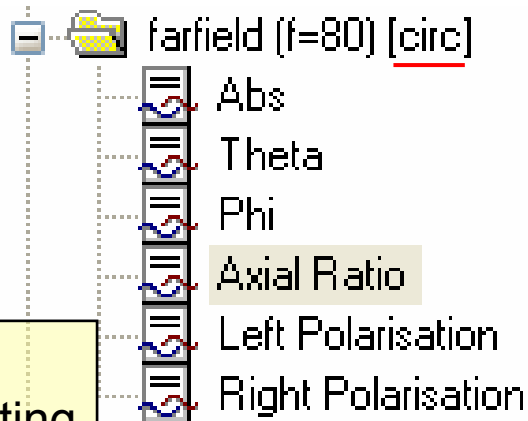

- + only one run required
- produces F-Parameters (no S-Parameters)
- constant phase shift only valid for one frequency
- different am/ph combination requires new run

Farfield Capabilities for circular polarized Antennas

Summary

- Antenna Farfield can be recorded in time and frequency domain (Probe / Monitor)
- Postprocessing templates automate result extraction (e.g. broadband farfield)
- checklist for accurate farfield:
 - energy decayed to -40dB [-60dB] ?
 - enough surrounding space ($\lambda/8$) – open (add space)?
 - Is antenna radiating at this frequency? (S-balance < 1 ?)
- Advanced capabilities to extract:
co+cross-pol / phase center / Grasp input data
RL pol / axial ratio
